

Mac App Store

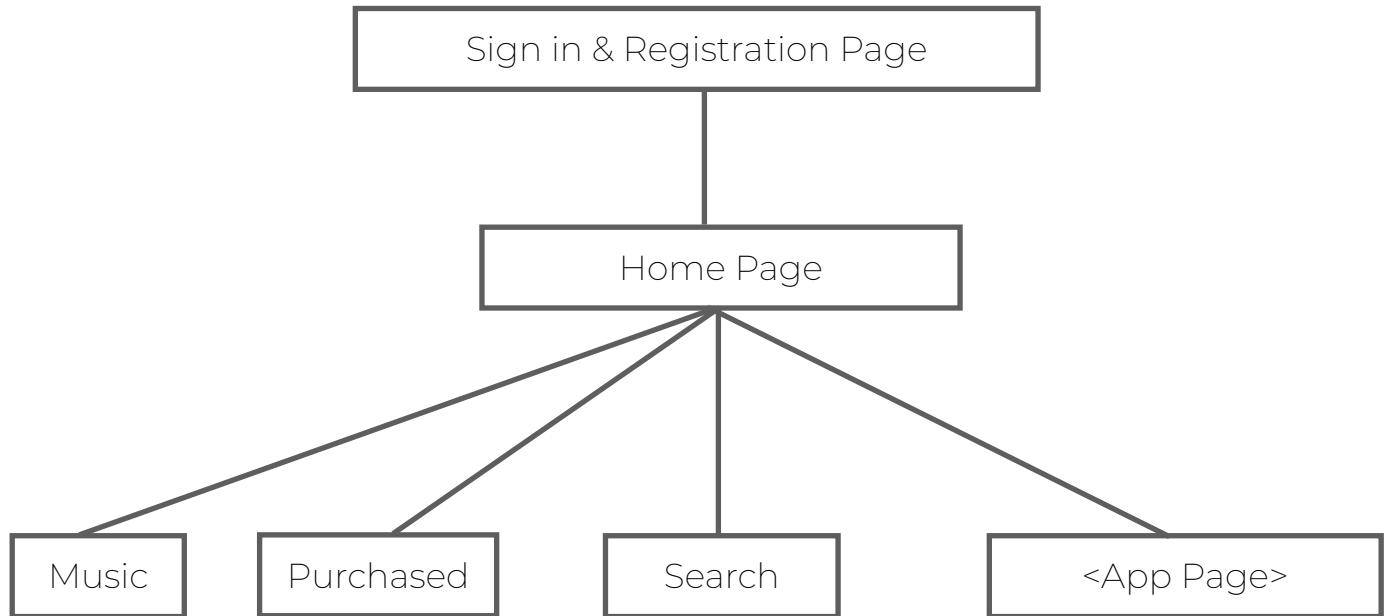

Website Developer: Bikram Chatterjee

Site Overview:

The Mac App Store website aims to be a hub for users to discover absolutely any app available on the actual Mac App Store and at the same time, serve as a place where they can find songs via a dedicated Apple Music Section. Users can also download their purchased apps from a dedicated purchased section. The Mac App Store's minimalistic design coupled with its features such featured, top charts, categories, search, and Apple Music will help users find their next app or song in no time.

Page Hierarchy and Navigation

Note: This is just the primary hierarchy. Almost all pages can be accessed from any other page in the website through the buttons in the top menu bar or app icons.

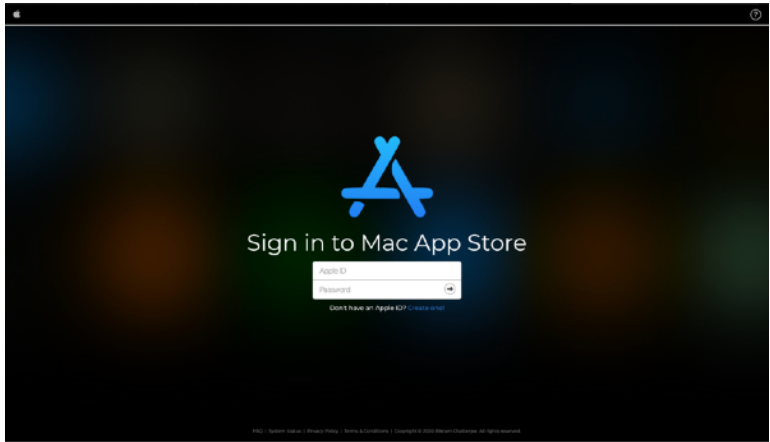

Implementation Specifications

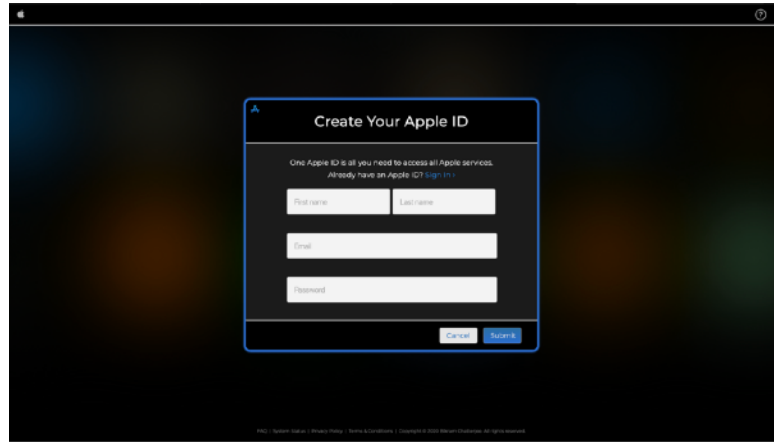

Technical Architecture:

- HTML (All Pages)
- CSS (All Pages)
- Javascript (All Pages)
- jQuery (All Pages)
- PHP. (Login/Registration Page & Logout Function)
- Local Storage (Home Page, Search Page, App Page, and Purchased Page)
- iTunes API (All Pages Except Login & Registration)

Page Design and Layout

Business Process/Logic Design

User Authentication (Login/Registration):

- PHP is used to store credentials in session cookies after user registers for a new account.
- Bcrypt is used will hash the password submitted by the user during registration and then compare the hash with the stored hash when the user wishes to sign in.
- Registration page requires a valid looking email address and a strong password in order for the user to successfully create a new account.
- User is not allowed to go back to the Sign in/Registration Page until the user is logged out. User is also not allowed to go to any other page except the login/registration unless the user is signed in.

Dynamic Webpages:

- **Login/Registration:** If the user clicks on the “Create One!” link to register a new account, a new registration window will pop up and replace the existing login body. Closing the registration window will make it disappear and show the login window again.
- **Search:** Searching for an app on the home page will clear existing content in the body and show the app (if found) with a link to the app’s page. Closing the search window will bring the user back to the previous screen.
- **App Page:** Upon clicking on any app on the website, the user will be directed to a dynamic webpage showing the description, screenshots, reviews, etc. of that particular app only.
- **Music Page:** This page dynamically changes when the user searches for music. This page also dynamically changes back and forth between itself and the search page according to the user’s actions.
- **Purchases Page:** This page dynamically changes back and forth between itself and the search page according to the user’s actions.

API/AJAX:

- The iTunes API is accessed using a AJAX method to retrieve data about all apps and songs across the website which is then inserted into html code via jQuery.

Scrolling:

- Clicking the left and right buttons in the Home Page will smoothly scroll the content left and right. The buttons will also fade and reappear according to the content's position.

Local Storage:

- Information about the app page the user wants to visit or the apps that the user has purchased is stored in the local storage and is used by various pages to retrieve that specific app data.

Summary

The biggest challenge while completing this project for me was figuring out how to retrieve the data from the iTunes API and then dynamically insert it into the HTML code. As a new website developer, designing the website itself was extremely time consuming as I needed to align and space everything evenly, down to each and every pixel. Another challenging thing was figuring out the horizontal scroll in the homepage such that the left and right buttons appear or fade according to the scrollable content's position.

I learned a lot about jQuery methods and how we can store data in local storage. Furthermore, I also learned more about CSS such as how to hide the browser's scroll bar or use flexbox to space things out evenly. Dynamic content was also new and fascinating to me as it was almost magical when the website's content got replaced without any reloading at all.

In future versions, I would like to improve the music page such that it uses an external plugin to play and control song previews from iTunes. Next, I would like to implement a special section dedicated to developers that will allow them to sign up, grow their business with resources (videos or documentation) designed to help them create incredible apps, and finally distribute their apps to the users after agreeing to meet the Mac App Store's design and review guidelines. Lastly, I would also like to develop a separate dynamic category page which shows apps based on the user's selected category.
